

Meta is building a *computer* that uses your Mac.

*The Muse desktop app already ships the entire code to see your screen, click, type, run programs, and drive a browser. Every switch is flipped **off** from a Meta server — and I found the switches.*

METHOD

Binary + server-flag teardown

SUBJECT

Muse 1.0 · codename “Endo”

CONFIDENCE

Found in code, unshipped

READING TIME

~6 minutes

01

UNRELEASED · FOUND IN CODE

THE FIVE DARK SWITCHES

Computer control is written, wired, and turned off at the server.

Muse ships its feature gates in a Meta config file (`endo-values-public`) that the app re-downloads on every launch. Five booleans in the `hatch_desktop` namespace decide whether Muse can operate the machine — and all five arrive **false**:

`enable_computer_control`

FALSE

`endo_enable_screen_recording`

FALSE

`enable_browser_automation`

FALSE

`endo_system_run_sandbox_enabled`

FALSE

`endo_enable_computer_use_onboarding`

FALSE

Source · Muse 1.0 MobileConfig cache `~/Library/Caches/com.meta.endo/MobileConfig/endo-values-public-956902cf.json` , read Sept 17 2026. Values re-fetched from Meta every launch.

02

SYSTEM.RUN · SANDBOXED EXECUTION

It can run programs — one at a time, on a leash.

```
> muse: system.run
"Execute a single program with argv-style arguments.
Shell operators, redirects, pipes, globbing, and
environment expansion are not supported."

"AppleScript (osascript / osacompile) and `open -a`
app launches are REJECTED in background mode."

gate: hatch_desktop:endo_system_run_sandbox_enabled = false
```

The design is deliberately narrow: no shell string, no `-c`, argv only — so pipes and redirects an app blocklist can't see never run. It's an execution primitive built for a careful rollout, not a terminal.

03

VISION · IT WANTS TO WATCH THE SCREEN

ScreenCaptureKit is linked. The overlay is coded. The grant is asked for.

The binary imports Apple’s modern screen-capture stack and the calls that request the permission at runtime — plus an on-screen “I’m looking” overlay and an accessibility-first click mode. Everything a computer-use agent needs to see a Mac is present:

```
SCShareableContent
```

```
/
```

```
SCStreamConfiguration
```

LINKED

```
CGRequestScreenCaptureAccess
```

LINKED

```
[ComputerUse] Display assertion acquired
```

STRING

```
_showComputerUseOverlay
```

STRING

```
_preferAXForComputerUseClicks
```

STRING

Yet `environment.describe` reports `screen_recording: false` even after the macOS permission is granted — because the gate above overrides it.

BROWSER AUTOMATION

Muse can drive a Chromium over the DevTools protocol — on loopback.

A second withheld capability: the app carries browser-automation plumbing that speaks CDP to a local debug endpoint. The gate is its own flag, separate from computer control — a hint the two ship independently.

`--remote-debugging-address=127.0.0.1`

Paired with `enable_browser_automation = false`, this is the same shape as every agentic-browser feature of 2026: a headed browser the model steers, kept on localhost so nothing's exposed.

05

ALREADY LIVE · THE 51-COMMAND CATALOG

What Muse can do today, before any switch flips.

With computer-use gated off, the agent still exposes a 51-command device catalog. This is the surface that already works on a permissioned Mac:

CALENDAR

create · delete · search · update

REMINDERS

create · complete · delete · list · update

CONTACTS

create · delete · search · update

NOTES

append · create · folders · read · search · update

IMESSAGE

send · search · threads · attachment · save

EMAIL

read · search · send · delete · status

FILES

read · write · edit · copy · rename · trash · upload · search · mkdir

ALSO

camera.snap · whatsapp.search · media_library.sync · system.notify · environment.describe · connection.health/repair

06

VOICE · TWO SEPARATE STACKS

Real-time speech in, real-time speech out.

Beyond computer-use, the binary reveals a full voice roadmap — dictation and a duplex speech-to-speech engine with a named voice:

Dictation →

```
wss://shortwave.facebook.com/voyager/v1/asr/duplex
```

VOYAGER

Model

```
prod_hatch_macos
```

.

```
voyager_dictation_use_abra_auth
```

ASR

Real-time S2S engine “Alo” .

```
aloS2SModelId
```

DUPLEX

Voice id

```
avocado_v2:MAI_02
```

.

```
enable_ptt_s2s
```

PUSH-TO-TALK

UNDER THE HOOD

The agent doesn't run on your Mac. It runs in a Meta VM.

The reason a local flag can't force computer-use on: the agent itself lives in a per-user cloud VM, reached over a Noise-encrypted WebSocket gateway. The Mac is a set of hands; the brain is server-side.

Per-user VM

`HATCH.METAAIVM.COM`

Transport

`TIGON HTTP · NOISE WSS GATEWAY`

Auth backend

`META "PROTON" · API.META.AI/PROTON`

Chat / agent API

`HATCH-API.META.AI`

The config that withholds computer-use rides the same edge as login and session-refresh — so it can't be blocked without killing the app.

08

THE TELL

Employees first. This is a staged rollout, not a dead feature.

Two flags in the same config give the release plan away — an onboarding flow that’s built but hidden, and an **employee** switch that ships in the public build:

```
hatch_desktop:endo_enable_computer_use_onboarding  
hatch_desktop:voyager_is_employee
```

An onboarding gate implies a first-run “let Muse control your Mac” walkthrough already exists. An employee gate implies Meta staff are testing it now, ahead of a cohort rollout to everyone else.

09

BY THE NUMBERS

5

capability switches shipped, all off

51

device commands already live

1

cloud VM per user runs the agent

0

of it toggleable from your machine

Source · aggregate of this teardown, Sept 17 2026. All figures measured, not estimated.

That's the teardown.

Everything here was read out of the shipping Muse 1.0 build and its Meta-served config on one Mac — the code for a screen-seeing, click-making, program-running, browser-driving desktop agent, sitting behind five server switches Meta hasn't flipped for the public. Found in code is not shipped: names, gates, and plans change, and some features never leave the lab. But the scaffolding is real, and it is waiting.

TEARDOWN DISPATCH · SEPT 17 2026 · UNAFFILIATED WITH META · INFERRED FROM DISABLED FLAGS
